$(\ell, 0)$-CARTER PARTITIONS, A GENERATING FUNCTION, AND THEIR CRYSTAL THEORETIC INTERPRETATION

CHRIS BERG AND MONICA VAZIRANI

Abstract. In this paper we give an alternate combinatorial description of the "$(\ell, 0)$-Carter partitions" (see [4]). Our main theorem is the equivalence of our combinatoric and the one introduced by James and Mathas ([7]). The condition of being an $(\ell, 0)$-Carter partition is fundamentally related to the hook lengths of the partition. The representation-theoretic significance of their combinatoric on an ℓ-regular partition is that it indicates the irreducibility of the corresponding specialized Specht module over the finite Hecke algebra (see [7]). We use our result to find a generating series which counts the number of such partitions, with respect to the statistic of a partition's first part. We then apply our description of these partitions to the crystal graph $B(\Lambda_0)$ of the basic representation of $\widehat{\mathfrak{sl}_\ell}$, whose nodes are labeled by ℓ-regular partitions. Here we give a fairly simple crystal-theoretic rule which generates all $(\ell, 0)$-Carter partitions in the graph $B(\Lambda_0)$. Finally, we mention how our construction can be generalized to recent results of M. Fayers (see [4]) and S. Lyle (see [11]) to count the total number of (not necessarily ℓ-regular) Specht modules which stay irreducible at a primitive ℓth root of unity (for $\ell > 2$).

1. Introduction

1.1. **Preliminaries.** Let λ be a partition of n and $\ell \geq 2$ be an integer. We will use the convention (x, y) to denote the box which sits in the x^{th} row and the y^{th} column of the Young diagram of λ. Throughout this paper, all of our partitions are drawn in English notation. $\mathcal{P}$ will denote the set of all partitions. An *ℓ-regular partition* is one in which no part occurs ℓ or more times. The length of a partition λ is defined to be the number of nonzero parts of λ and is denoted $len(\lambda)$.

The *hook length* of the (a, c) box of λ is defined to be the number of boxes to the right and below the box (a, c), including the box (a, c) itself. It is denoted $h^{\lambda}_{(a,c)}$.

A *removable ℓ-rim hook* in λ (also called an ℓ-ribbon of λ) is a connected sequence of ℓ boxes in the Young diagram of λ, containing no 2×2 square, such that when removed from λ, the remaining diagram is the Young diagram of some other partition. We will often abbreviate and call a removable ℓ-rim hook an ℓ-rim hook.

Any partition which has no removable ℓ-rim hooks is called an *ℓ-core*. Every partition λ has a well defined ℓ-core, which is obtained by removing ℓ-rim hooks from the outer edge while at each step the removal of a hook is still a (non-skew) partition. The ℓ-core is uniquely determined from the partition, independently of choice of the order in which one successively removes ℓ-rim hooks. The number of ℓ-rim hooks which must be removed from a partition λ to obtain its core is called the *weight* of λ. The set of all ℓ-cores is denoted $\mathcal{C}_\ell$. See [6] for more details.

Removable ℓ-rim hooks which are flat (i.e. those whose boxes all sit in one row) will be called *horizontal ℓ-rim hooks*. These are also commonly called ℓ-ribbons

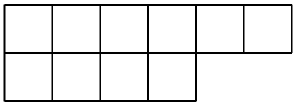
with spin 0. Removable ℓ-rim hooks which are not flat will be called *non-horizontal ℓ-rim hooks*.

Definition 1.1.1. An *ℓ-partition* is an ℓ-regular partition which

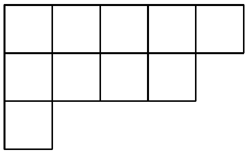
- Has no non-horizontal ℓ-rim hooks.
- After removing any number of horizontal ℓ-rim hooks, the remaining diagram has no non-horizontal ℓ-rim hooks.

Example 1.1.2. Any ℓ-core is also an ℓ-partition.

Example 1.1.3. $(6,4)$ is a 3-partition, as well as a ℓ-partition for $\ell > 7$ but is not a $2,4,5,6,7$-partition. It is an ℓ-core for $\ell > 7$.



Example 1.1.4. $(5,4,1)$ is a 6-core, hence a 6-partition. It is a 2-partition, but not a 2-core. It is not a 3,4,5,7-partition. It is an ℓ-core for $\ell > 7$.



Definition 1.1.5. For a fixed field $\mathbb{F}$ and $0 \neq q \in \mathbb{F}$, the finite Hecke Algebra $H_n(q)$ is defined to be the algebra over $\mathbb{F}$ generated by $T_1, ..., T_{n-1}$ with relations

$$\begin{array}{ll} T_iT_j = T_jT_i & \text{for } |i-j| > 1 \\ T_iT_{i+1}T_i = T_{i+1}T_iT_{i+1} & \text{for } i < n-1 \\ T_i^2 = (q-1)T_i + q & \text{for } i \leq n-1. \end{array}$$

In this paper we will always assume that $q \neq 1$, that $q \in \mathbb{F}$ is a primitive ℓth root of unity (so necessarily $\ell \geq 2$) and that the characteristic of $\mathbb{F}$ is zero.

Similar to the symmetric group, a construction of the Specht module $S^\lambda = S^\lambda[q]$ exists for $H_n(q)$ (see [3]). For $k \in \mathbb{Z}$, let

$$\nu_\ell(k) = \begin{cases} 1 & \ell \mid k \\ 0 & \ell \nmid k. \end{cases}$$

It is known that the Specht module S^λ indexed by an ℓ-regular partition λ is irreducible if and only if

$$(\star) \quad \nu_\ell(h_{(a,c)}) = \nu_\ell(h_{(b,c)}) \quad \text{for all pairs } (a,c),\ (b,c) \in \lambda$$

(see [7]). Partitions which satisfy $(\star)$ have been called in the literature $(\ell, 0)$-Carter partitions. So, an equivalent condition for the irreducibility of the Specht module indexed by an ℓ-regular partition is that the hook lengths in a column of the partition λ are either all divisible by ℓ or none of them are, for every column (see [4] for general partitions, when $\ell \geq 3$).

All of the irreducible representations of $H_n(q)$ have been constructed abstractly when q is a primitive ℓth root of unity. These modules are indexed by ℓ-regular partitions λ, and are called D^λ. D^λ is the unique simple quotient of S^λ (see [3] for more details). In particular $D^\lambda = S^\lambda$ if and only if S^λ is irreducible and λ is ℓ-regular.

Let $\nu'_p(k) = max\{m : \ p^m \mid k\}$. In the symmetric group setting, for a prime p, the requirement for the irreducibility of the Specht module indexed by a p-regular partition over the field $\mathbb{F}_p$ is that

$$\nu'_p(h_{(a,c)}) = \nu'_p(h_{(b,c)}) \quad \text{for all pairs } (a,c),\ (b,c) \in \lambda$$

(see [6]).

Note that ν_ℓ is related to ν'_ℓ in that $\nu_\ell(k) = \max\{m : [\ell]_z^m \mid [k]_z\}$, where z is an indeterminate and $[k]_z = \frac{z^k-1}{z-1} \in \mathbb{C}[z]$.

From Example 2 above, we can see that $S^{(5,4,1)}$ is irreducible over $H_{10}(-1)$, but it is reducible over $\mathbb{F}_2 S_{10}$. This makes the problem of determining the irreducible Specht modules different for $\mathbb{F}_p S_n$ and $H_n(q)$ where $q = e^{\frac{2\pi i}{p}}$. This paper restricts its attention to $H_n(q)$.

1.2. **Main results.** Here we summarize the main results of this paper. Section 2 shows the equivalence of ℓ-partitions and $(\ell, 0)$-Carter partitions (see Theorem 2.1.6). Section 3 gives a different classification of ℓ-partitions which allows us to give an explicit formula for a generating function for the number of ℓ-partitions with respect to the statistic of a partitions first part. Finally, in Section 4 we give a crystal theoretic interpretation of ℓ-partitions. There we explain where in the crystal graph $B(\Lambda_0)$ one can expect to find ℓ-partitions (see Theorems 4.3.1, 4.3.2 and 4.3.3).

2. ℓ-PARTITIONS

We now claim that a partition is an ℓ-partition if and only if it satisfies $(\star)$ (We drop the $(\ell, 0)$-Carter partition notation and just use the combinatorial condition of $(\star)$). To prove this, we will first need two lemmas which tell us when we can add/remove horizontal ℓ-rim hooks to/from a diagram.

2.1. Equivalence of the combinatorics.

Lemma 2.1.1. *For λ a partition which does not satisfy $(\star)$, if we add a horizontal ℓ-rim hook to λ to form a new partition μ, μ will also not satisfy $(\star)$.*

Proof. If λ does not satisfy $(\star)$, it means that somewhere in the partition there are two boxes (a,c) and (b,c) with ℓ dividing exactly one of $h^\lambda_{(a,c)}$ and $h^\lambda_{(b,c)}$. We will assume $a < b$. Here we prove the case that $\ell \mid h^\lambda_{(a,c)}$ and $\ell \nmid h^\lambda_{(b,c)}$, the other case being similar.

Case 1. It is easy to see that adding a horizontal ℓ-rim hook in row i for $i < a$ or $a < i < b$ will not change the hook lengths in the boxes (a,c) and (b,c). In other words, $h^\lambda_{(a,c)} = h^\mu_{(a,c)}$ and $h^\lambda_{(b,c)} = h^\mu_{(b,c)}$.

Case 2. If the horizontal ℓ-rim hook is added to row a, then $h^\lambda_{(a,c)} + \ell = h^\mu_{(a,c)}$ and $h^\lambda_{(b,c)} = h^\mu_{(b,c)}$. Similarly if the new horizontal ℓ-rim hook is added in row b, $h^\lambda_{(a,c)} = h^\mu_{(a,c)}$ and $h^\lambda_{(b,c)} + \ell = h^\mu_{(a,c)}$. Still, $\ell \mid h^\mu_{(a,c)}$ and $\ell \nmid h^\mu_{(b,c)}$.

Case 3. Suppose the horizontal ℓ-rim hook is added in row i with $i > b$. If the box (i, c) is not in the added ℓ-rim hook then $h^{\lambda}_{(a,c)} = h^{\mu}_{(a,c)}$ and $h^{\lambda}_{(b,c)} = h^{\mu}_{(b,c)}$. If the box (i, c) is in the added ℓ-rim hook, then there are two sub-cases to consider. If (i, c) is the rightmost box of the added ℓ-rim hook then $\ell \mid h^{\mu}_{(a,c-\ell+1)}$ and $\ell \nmid h^{\mu}_{(b,c-\ell+1)}$. Otherwise (i, c) is not at the end of the added ℓ-rim hook, in which case $\ell \mid h^{\mu}_{(a,c+1)}$ and $\ell \nmid h^{\mu}_{(b,c+1)}$. In all cases, μ does not satisfy $(\star)$. □

Example 2.1.2. Let $\lambda = (14, 9, 5, 2, 1)$ and $\ell = 3$. This partition does not satisfy $(\star)$. For instance, looking at boxes $(2, 3)$ and $(3, 3)$, we see that $3 \mid h^{\lambda}_{(3,3)} = 3$ but $3 \nmid h^{\lambda}_{(2,3)} = 8$. Let $\lambda[i]$ denote the partition obtained when adding a horizontal ℓ-rim hook to the ith row of λ (when it is still a partition). Adding a horizontal 3-rim hook in row 1 will not change $h^{\lambda}_{(2,3)}$ or $h^{\lambda}_{(3,3)}$ (Case 1 of Lemma 2.1.1). Adding a horizontal 3-rim hook to row 2 will make $h^{\lambda[2]}_{(2,3)} = 11$, which is equal to $h^{\lambda}_{(2,3)}$ mod 3 (Case 2 of Lemma 2.1.1). Adding in row 3 is also Case 2. Adding a horizontal 3-rim hook to row 4 will make $h^{\lambda[4]}_{(2,3)} = 9$ and $h^{\lambda[4]}_{(3,3)} = 4$, but one column to the right, we see that now $h^{\lambda[4]}_{(2,4)} = 8$ and $h^{\lambda[4]}_{(3,4)} = 3$ (Case 3 of Lemma 2.1.1).

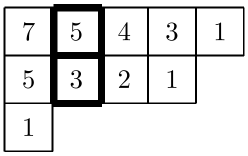
1													

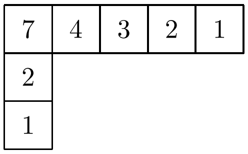
Lemma 2.1.3. *Suppose λ does not satisfy $(\star)$. Suppose $a < b$ and suppose that ℓ divides exactly one of $h^{\lambda}_{(a,c)}$ and $h^{\lambda}_{(b,c)}$. Let ν be λ with a removed horizontal ℓ-rim hook (if a horizontal ℓ-rim hook exists). Then, as long as ν still has the box (b, c), ν does not satisfy $(\star)$.*

Proof. All cases are done similar to the proof of Lemma 2.1.1. The only case which does not apply is when you remove a horizontal strip from row b and remove the box (b, c). □

Remark 2.1.4. In the proof of Lemma 2.1.1 we have also shown that when adding a horizontal ℓ-rim hook to a partition which does not satisfy $(\star)$, the violation to $(\star)$ occurs in the same rows as the original partition. It can also be shown in Lemma 2.1.3 that when removing a horizontal ℓ-rim hook (in the cases above), the violation will stay in the same rows as the original partition. This will be useful in the proof of Theorem 2.1.6.

Example 2.1.5. $(5, 4, 1)$ does not satisfy $(\star)$ for $\ell = 3$. The boxes $(1, 2)$ and $(2, 2)$ are a violation of $(\star)$. Removing a horizontal 3-rim hook will give the partition $(5, 1, 1)$ which does satisfy $(\star)$. Note that this does not violate Lemma 2.1.3, since the removed horizontal 3-rim hook contains the box $(2,2)$.





Theorem 2.1.6. *A partition is an ℓ-partition if and only if it satisfies $(\star)$.*

Proof. Let λ be an ℓ-regular partition.
$\Leftarrow$ Suppose λ is not an ℓ-partition. If λ is not ℓ-regular then let i be given so that $\lambda_i = \lambda_{i+1} = \cdots = \lambda_{i+\ell-1} \neq 0$. Then exactly one of $h^{\lambda}_{(i,\lambda_i)}, h^{\lambda}_{(i+1,\lambda_i)}, \ldots, h^{\lambda}_{(i+\ell-1,\lambda_i)}$ is divisible by ℓ. Therefore, λ does not satisfy $(\star)$.

Otherwise, suppose λ is ℓ-regular and a non-horizontal ℓ-rim hook can be removed from λ, with upper rightmost box (a,c) and lower leftmost box (b,d) with $a < b$ and $c \geq d$. Then $h^{\lambda}_{(a,d)} = \ell$ and $h^{\lambda}_{(b,d)} < \ell$ so λ does not satisfy $(\star)$. If no non-horizontal ℓ-rim hooks appear immediately in the partition, then remove horizontal ℓ-rim hooks from λ until you obtain a partition μ with a non-horizontal ℓ-rim hook. Then by the same argument, μ does not satisfy $(\star)$. Now add back to μ the horizontal ℓ-rim hooks which were removed from λ. By Lemma 2.1.1, each time a horizontal ℓ-rim hook is added to μ the resulting partition will not satisfy $(\star)$. Thus λ does not satisfy $(\star)$.

$\Rightarrow$ Suppose λ is an ℓ-partition and that λ does not satisfy $(\star)$. We will suppose that there exists boxes (a,c) and (b,c) in λ so that ℓ divides exactly one of $h^{\lambda}_{(a,c)}$ and $h^{\lambda}_{(b,c)}$.

Case 1. Suppose that $a < b$ and that $\ell \mid h^{\lambda}_{(a,c)}$. Then without loss of generality we may assume that $b = a+1$. We leave to the interested reader the proof of the fact that if $\ell \mid h^{\lambda}_{(a,c)}$ then there exists at least one removable ℓ-rim hook in the Young diagram for λ (see [6]). By assumption it must be horizontal. If one exists which does not contain the box (b,c) then remove it and let $\lambda^{(1)}$ be λ without this ℓ-rim hook. By Lemma 2.1.3, as long as we did not remove the (b,c) box, $\lambda^{(1)}$ will still not satisfy $(\star)$. Then there are boxes (a,c_1) and (b,c_1) for which $\ell \mid h^{\lambda^{(1)}}_{(a,c_1)}$ but $\ell \nmid h^{\lambda^{(1)}}_{(b,c_1)}$. Remark 2.1.4 above explains why we can assume that the violation to $(\star)$ are in the same rows a and b of $\lambda^{(1)}$. We apply the same process as above repeatedly until we can remove a horizontal ℓ-rim hook from the partition $\lambda^{(k)}$ which contains the (b,c_k) box (i.e. we are not in the case where we can apply Lemma 2.1.3) and cannot remove a horizontal ℓ-rim hook from row a. Let d be so that $h_{(b,d)} = 1$. Such a d must exist since we are removing a horizontal ℓ-rim hook from this row. Since (b,c_k) is removed from $\lambda^{(k)}$ when we remove the horizontal ℓ-rim hook, $h^{\lambda^{(k)}}_{(b,c_k)} < \ell$ (ℓ does not divide $h^{\lambda^{(k)}}_{(b,c_k)}$ by assumption, so in particular $h^{\lambda^{(k)}}_{(b,c_k)} \neq \ell$). Note that $h^{\lambda^{(k)}}_{(a,c_k)} = h^{\lambda^{(k)}}_{(b,c_k)} + h^{\lambda^{(k)}}_{(a,d)} - 1$, $\ell \mid h^{\lambda^{(k)}}_{(a,c_k)}$ and $\ell \nmid h^{\lambda^{(k)}}_{(b,c_k)}$, so $\ell \nmid (h^{\lambda^{(k)}}_{(a,d)} - 1)$. If $h^{\lambda^{(k)}}_{(a,d)} - 1 > \ell$ then we could remove a horizontal ℓ-rim hook from row a, which we cannot do by assumption. Otherwise $h^{\lambda^{(k)}}_{(a,d)} < \ell$. Then a non-horizontal ℓ-rim hook exists starting at the rightmost box of the ath row, going left to (a,d), down to (b,d) and then left until you have covered ℓ boxes. This is a contradiction as we have assumed that λ was an ℓ-partition.

Case 2. Suppose that $a < b$ and that $\ell \mid h^{\lambda}_{(b,c)}$. We will reduce this to Case 1. Without loss of generality we may assume that $b = a+1$ and that $\ell \mid h^{\lambda}_{(n,c)}$ for all $n > a$ (otherwise we are in Case 1). Let m be so that $(m,c) \in \lambda$ but $(m+1,c) \notin \lambda$. Then because $h^{\lambda}_{(m,c)} \geq \ell$, the list $h^{\lambda}_{(a,c)}, h^{\lambda}_{(a,c+1)} = h^{\lambda}_{(a,c)} - 1, \ldots, h^{\lambda}_{(a,c+\ell-1)} = h^{\lambda}_{(a,c)} - \ell + 1$ consists of ℓ consecutive integers. Hence one of them must be divisible by ℓ. Say it is $h^{\lambda}_{(a,c+i)}$. Also $\ell \nmid h^{\lambda}_{(m,c+i)}$, since $h^{\lambda}_{(m,c+i)} = h^{\lambda}_{(m,c)} - i$ and $\ell \mid h^{\lambda}_{(m,c)}$. Then we may apply Case 1 to the boxes $(a,c+i)$ and $(m,c+i)$.

□

Remark 2.1.7. This result can actually be obtained using a more general result of James and Mathas ([7], Theorem 4.20), where they classified which S^{λ} remain irreducible for λ ℓ-regular. However, we have included this proof to emphasize the simplicity of the theorem and its simple combinatorial proof in this context.

Remark 2.1.8. When q is a primitive ℓth root of unity, and λ is an ℓ-regular partition, the Specht module S^{λ} of $H_n(q)$ is irreducible if and only if λ is an ℓ-partition. This follows from what was said above concerning the James and Mathas result on the equivalence of $(\star)$ and irreducibility of Specht modules, and Theorem 2.1.6.

3. GENERATING FUNCTIONS

Let $\mathcal{L}_\ell = \{\lambda \in \mathcal{P} : \lambda \text{ is an } \ell\text{-partition}\}$. In this section, we count ℓ-partitions via generating functions. We study the generating function with the statistic being the first part of the partition. Let $B_\ell(x) = \sum_{k=0}^{\infty} b^{\ell}_k x^k$ where $b^{\ell}_k = \#\{\lambda : \lambda_1 = k, \lambda \in \mathcal{L}_\ell\}$ is the number of ℓ-partitions with the first part of the partition equal to k, i.e. $B_\ell(x) = \sum_{\lambda \in \mathcal{L}_\ell} x^{\lambda_1}$.

3.1. Counting ℓ-cores.

We will count ℓ-cores first, with respect to the statistic of the first part of the partition. Let

$$C_\ell(x) = \sum_{k=0}^{\infty} c^{\ell}_k x^k$$

where $c^{\ell}_k = \#\{\lambda \in \mathcal{C}_\ell : \lambda_1 = k\}$. Note that this does not depend on the size of the partition, only its first part. Also, the empty partition is considered as the unique partition with first part 0, and is always a core, so that $c^{\ell}_0 = 1$ for every ℓ.

Example 3.1.1. For $\ell = 2$, all 2-cores are staircases, i.e. are of the form $\lambda = (k, k-1, \ldots, 2, 1)$. Hence $C_2(x) = \sum_{k=0}^{\infty} x^k = \frac{1}{1-x}$.

Example 3.1.2. For $\ell = 3$, the first few cores are

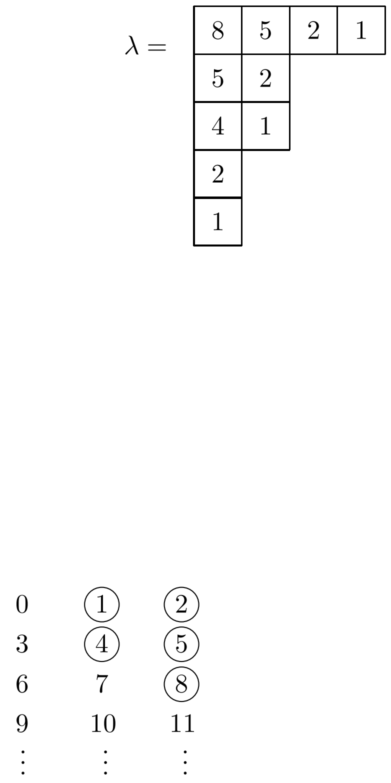
$$\emptyset, (1), (1,1), (2), (2,1,1), (2,2,1,1), (3,1), (3,1,1), (3,2,2,1,1), (3,3,2,2,1,1), \ldots$$

so $C_3(x) = 1 + 2x + 3x^2 + 4x^3 + \ldots$

For a partition $\lambda = (\lambda_1, \ldots, \lambda_s)$, the *$\beta$-numbers* $(\beta_1, \ldots, \beta_s)$ of λ are defined to be the hook lengths of the first column (i.e. $\beta_i = h^{\lambda}_{(i,1)}$). Note that this is a simplified version of the β-numbers defined by James and Kerber in [6], where all definitions in this section can be found. We draw a diagram ℓ columns wide with the numbers

$\{0, 1, 2, \ldots, \ell-1\}$ inserted in the first row in order, $\{\ell, \ell+1, \ldots, 2\ell-1\}$ inserted in the second row in order, etc. Then we circle all of the β-numbers for λ. The columns of this diagram are called *runners*, the circled elements are called *beads*, and the diagram is called an *abacus* . It is well known that a partition λ is an ℓ-core if and only if all of the beads lie in the last $\ell-1$ runners and if any bead is in the abacus, then all of the numbers above it in the same runner also have beads.

Example 3.1.3. $\lambda = (4, 2, 2, 1, 1)$ has β-numbers $8, 5, 4, 2, 1$, and for $\ell = 3$ our abacus has the first runner empty, the second runner has beads at 1 and 4, and the third runner has beads at 2,5 and 8 (as pictured below). Hence this is a 3-core.



Young diagram and abacus of $\lambda = (4, 2, 2, 1, 1)$

Recall that $c^\ell_k = \#\{\lambda \in \mathcal{C}_\ell : \lambda_1 = k\}$.

Proposition 3.1.4. $c^\ell_k = \binom{k+\ell-2}{k}$.

Proof. This proof is by induction on ℓ. For $\ell = 2$ this was done in the examples above. We next show the relation:

$$(\sharp) \qquad c^\ell_k = \sum_{j=0}^{k} c^{\ell-1}_j$$

This will prove the result, using induction on all the terms on the right hand side and the fact that $\binom{\ell+k-2}{k} = \binom{\ell-3}{0} + \binom{\ell-2}{1} + \cdots + \binom{\ell+k-3}{k}$. We give a bijective proof of this relation. Using the abacus description of cores, we describe our bijection as follows:

Given an ℓ-core with largest part k, remove the whole runner which contains the largest bead (the bead with the largest β-number). The remaining runners can be placed into an $\ell - 1$ abacus in order. The remaining abacus will clearly have its first runner empty. This will correspond to an (ℓ - 1)-core with largest part at most k. This map gives a bijection between the set of all ℓ-cores with largest part k and the set of all (ℓ-1)-cores with largest part at most k.

The set of all $(\ell - 1)$-cores with largest part at most k has cardinality equal to the right hand side of ($\sharp$), by induction. Therefore, the set of all ℓ-cores with largest part k has cardinality $\binom{k+\ell-2}{k}$. $\square$

Remark 3.1.5. The bijection above between ℓ-cores with first part k and $(\ell - 1)$-cores with first part $\leq k$ has several other beautiful descriptions, using different interpretations of ℓ-cores. We plan on including these other descriptions in a later paper. See [1] for more details.

Example 3.1.6. Let $\ell = 3$ and $\lambda = (4, 2, 2, 1, 1)$. The abacus for λ is:

$$\begin{array}{ccc} 0 & \textcircled{1} & \textcircled{2} \\ 3 & \textcircled{4} & \textcircled{5} \\ 6 & 7 & \textcircled{8} \\ 9 & 10 & 11 \\ \vdots & \vdots & \vdots \end{array}$$

The largest β-number is 8. Removing the whole runner in the same column as the 8, we get the remaining diagram with runners relabeled for $\ell = 2$

$$\begin{array}{ccc} 0 & \textcircled{1} & \otimes \\ 2 & \textcircled{3} & \otimes \\ 4 & 5 & \otimes \\ 6 & 7 & \\ \vdots & \vdots & \end{array}.$$

These are the β-numbers for the partition $(2, 1)$, which is a 2-core with largest part ≤ 4.

From the above reasoning, we obtain $C_\ell(x) = \sum_{k\geq 0} \binom{k+\ell-2}{k} x^k$ and so conclude the following.

Proposition 3.1.7.

$$C_\ell(x) = \frac{1}{(1-x)^{\ell-1}}.$$

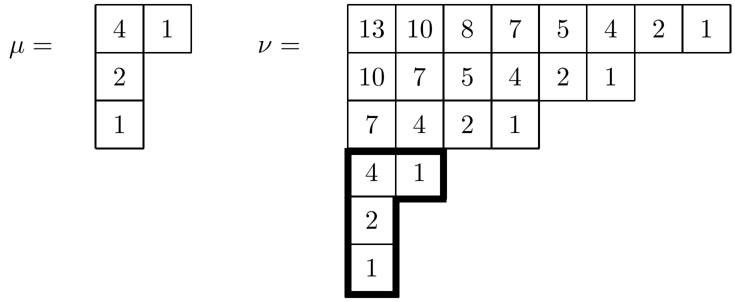
3.2. **Decomposing ℓ-partitions.** We now present our decomposition of ℓ-partitions. Let $\mu = (\mu_1, \ldots, \mu_s)$ to be any ℓ-core where $\mu_1 - \mu_2 \neq \ell - 1$. For an $r \geq 0$ we form a new ℓ-core $\nu = (\nu_1, \ldots \nu_r, \nu_{r+1}, \ldots, \nu_{r+s})$ by attaching r rows above μ so that $\nu_r = \mu_1 + \ell - 1, \nu_{r-1} = \mu_1 + 2(\ell - 1), \ldots \nu_1 = \mu_1 + r(\ell - 1)$ and $\nu_{r+i} = \mu_i$ for $i = 1, 2, \ldots, s$. Here r may be zero, in which case $\mu = \nu$. It can be shown that ν is an ℓ-core. Fix a partition $\kappa = (\kappa_1, \ldots, \kappa_{r+1})$ with at most $(r + 1)$ parts. Then a new partition λ is obtained from ν by adding κ_i horizontal ℓ-rim hooks to row i for every $i \in \{1, \ldots, r + 1\}$. In other words $\lambda_i = \nu_i + \ell\kappa_i$ for $i \in \{1, 2, \ldots, r + 1\}$ and $\lambda_i = \nu_i$ for $i > r + 1$.

From now on, when we associate λ with the triple (μ, r, κ), we will think of $\mu \subset \lambda$ as embedded in the rows below the rth row in λ. We introduce the notation $\lambda \approx (\mu, r, \kappa)$ for this decomposition.

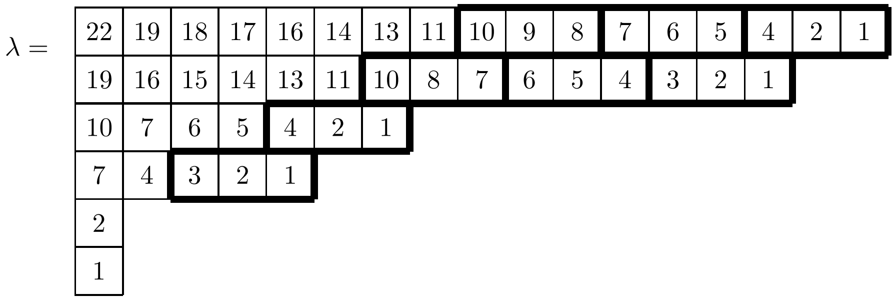
Theorem 3.2.1. *Let* μ*,* r *and* κ *be as above. Then* $\lambda \approx (\mu, r, \kappa)$ *is an* ℓ*-partition. Conversely, every* ℓ*-partition corresponds uniquely to a triple* (μ, r, κ)*.*

Proof. This follows from Theorem 2.1.6 ☐

Example 3.2.2. For $\ell = 3$, $\mu = (2, 1, 1)$ is a 3-core with $\mu_1 - \mu_2 \neq 2$. We may add three rows ($r = 3$) to it to obtain $\nu = (8, 6, 4, 2, 1, 1)$, which is still a 3-core. Now we may add three horizontal ℓ-rim hooks to the first row, three to the second, one to the third and one to the fourth ($\kappa = (3, 3, 1, 1)$) to obtain the partition $\lambda = (17, 15, 7, 5, 1, 1)$, which is a 3-partition.



$\mu \subset \nu$ is highlighted.



The 3-partition constructed above, with cells contributed by κ highlighted.

Remark 3.2.3. In the proofs of Theorems 4.3.1 and 4.3.3 we will prove that a partition is an ℓ-partition by giving its decomposition into (μ, r, κ).

3.3. **Counting ℓ-partitions.** We derive a closed formula for our generating function B_ℓ by using our ℓ-partition decomposition described above. First we note that if

$$C_\ell(x) = \sum_{\mu \in \mathcal{C}_\ell} x^{\mu_1} \quad \text{then} \quad x^{\ell-1} C_\ell(x) = \sum_{\mu \in \mathcal{C}_\ell \,:\, \mu_1 - \mu_2 = \ell - 1} x^{\mu_1}.$$

Therefore, $\displaystyle\sum_{\mu \in \mathcal{C}_\ell :\, \mu_1 - \mu_2 \neq \ell - 1} x^{\mu_1} = (1 - x^{\ell-1}) C_\ell(x)$. Hence the generating function for all cores μ with $\mu_1 - \mu_2 \neq \ell - 1$ is $\dfrac{1 - x^{\ell-1}}{(1-x)^{\ell-1}}$.

We are now ready to prove our closed formula for B_ℓ. First, recall that $B_\ell(x) = \sum b_n^\ell x^n$ where $b_n^\ell = \{\lambda \in \mathcal{L}_\ell : \lambda_1 = n\}$.

Theorem 3.3.1.

$$B_\ell(x) = \frac{1-x^{\ell-1}}{(1-x)^{\ell-1}(1-x^{\ell-1}-x^\ell)}.$$

Proof. We will follow our construction of ℓ-partitions from Section 3.2. Note that if $\lambda \approx (\mu, r, \kappa)$, then the first part of λ is $\mu_1 + \ell\kappa_1 + r(\ell-1)$. Hence λ contributes $x^{\mu_1+\ell\kappa_1+r(\ell-1)}$ to B_ℓ.

Fix a core μ with $\mu_1 - \mu_2 \neq \ell - 1$. Let r and κ_1 be fixed non-negative integers. Let γ_{r,κ_1} be the number of partitions with first part κ_1 and length less than or equal to $r+1$. γ_{r,κ_1} counts the number of ℓ-partitions with r and κ_1 fixed that can be constructed from μ. Note that γ_{r,κ_1} is independent of what μ is.

γ_{r,κ_1} is the same as the number of partitions which fit inside a box of size height r and width κ_1. Hence $\gamma_{r,\kappa_1} = \binom{r+\kappa_1}{r}$. Fixing μ and r as above, the generating function for the number of ℓ-partitions with core $(\mu, r, \emptyset)$ with respect to the number of boxes added to the first row is $\displaystyle\sum_{\kappa_1=0}^{\infty} \gamma_{r,\kappa_1} x^{\kappa_1 \ell} = \frac{1}{(1-x^\ell)^{r+1}}$.

Now for a fixed μ as above, the generating function for the number of ℓ-partitions which can be constructed from μ with respect to the number of boxes added to the first row is $\displaystyle\sum_{r=0}^{\infty} x^{r(\ell-1)} \frac{1}{(1-x^\ell)^{r+1}}$. Multiplying through by $1 - x^{\ell-1} - x^\ell$, one can check that

$$\sum_{r=0}^{\infty} x^{r(\ell-1)} \frac{1}{(1-x^\ell)^{r+1}} = \frac{1}{1-x^{\ell-1}-x^\ell}.$$

Therefore $B_\ell(x)$ is just the product of the two generating functions $(1-x^{\ell-1})C_\ell(x)$ and $\frac{1}{1-x^{\ell-1}-x^\ell}$. Hence

$$B_\ell(x) = \frac{1-x^{\ell-1}}{(1-x)^{\ell-1}(1-x^{\ell-1}-x^\ell)}.$$

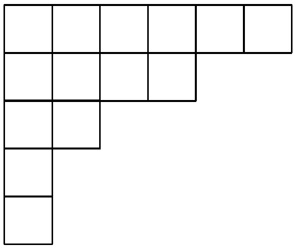
$\square$

3.4. **Counting ℓ-partitions of a fixed weight and fixed core.** Independently of the authors, Cossey, Ondrus and Vinroot have a similar construction of partitions associated with irreducible representations. In [2], they gave a construction analogous to our construction on ℓ-partitions from Section 3.2 for the case of the symmetric group over a field of characteristic p. After reading their work and noticing the similarity to our own, we decided to include the following theorem, which is an analogue of their theorem for symmetric groups. The statement is a direct consequence of our construction, so no proof will be included.

Corollary 3.4.1. *For a fixed core ν satisfying $\nu_i - \nu_{i+1} = \ell - 1$ for $i = 1, 2, \dots r$ and $\nu_{r+1} - \nu_{r+2} \neq \ell - 1$, the number of ℓ-partitions of a fixed weight w is the number of partitions of w with at most $r+1$ parts. The generating function for the number of ℓ-partitions of a fixed ℓ-core ν with respect to the statistic of the weight of the partition is thus $\displaystyle\prod_{i=1}^{r+1} \frac{1}{1-x^i}$. Hence the generating function for all $(\ell, 0)$-Carter* *partitions with fixed core* ν *with respect to the statistic of the size of the partition is* $\displaystyle\sum_{\lambda\in\mathcal{L}_\ell \text{ with core } \nu} x^{|\lambda|} = x^{|\nu|}\prod_{i=1}^{r+1}\frac{1}{1-x^{\ell i}}$.

Example 3.4.2. Let $\ell = 3$ and let $\nu = (6,4,2,1,1) \approx ((2,1,1),2,\emptyset)$ be a 3-core. Then the number of 3-partitions of weight 5 with core ν is exactly the number of partitions of 5 into at most 3 parts. There are 5 such partitions $((5),(4,1),(3,2),(3,1,1),(2,2,1))$. Therefore, there are 5 such ℓ-partitions. They are $(21,4,2,1,1)$, $(18,7,2,1,1)$, $(15,10,2,1,1)$, $(15,7,5,1,1)$ and $(12,10,5,1,1)$.

$\nu =$



For ν above, $r = 2$, so horizontal 3-rim hooks can be added to the first three rows.

4. The Crystal of the Basic Representation of $\widehat{\mathfrak{sl}_\ell}$

There is a crystal graph structure on the set of ℓ-regular partitions. In this section we examine the properties of ℓ-partitions in this crystal graph. In particular, just as one can obtain ℓ-cores by following an i-string from another ℓ-core, one can obtain ℓ-partitions by following an i-string from another ℓ-partition. However, more ℓ-partitions exist. Sometimes ℓ-partitions live one position before the end of an i-string (but nowhere else). In particular, there is not a nice interpretation in terms of the braid group orbits of nodes. In Theorem 4.3.3 we characterize (combinatorially) where this happens.

4.1. Description of crystal.

We will assume some familiarity with the theory of crystals (see [8]), and their relationship to the representation theory of the finite Hecke Algebra (see [5] or [9]). We will look at the crystal $B(\Lambda_0)$ of the irreducible highest weight module $V(\Lambda_0)$ of the affine Lie algebra $\widehat{\mathfrak{sl}_\ell}$ (also called the basic representation of $\widehat{\mathfrak{sl}_\ell}$). The set of nodes of $B(\Lambda_0)$ is denoted $B := \{\lambda \in \mathcal{P} : \lambda \text{ is } \ell\text{-regular}\}$. We will describe the arrows of $B(\Lambda_0)$ below. This description is originally due to Misra and Miwa (see [13]).

We now view the Young diagram for λ as a set of boxes, with their corresponding residues $b - a \mod \ell$ written into the box in row a and column b. A box x in λ is said to be a removable i-box if it has residue i and after removing x from λ the remaining diagram is still a partition. A box y not in λ is an addable i-box if it has residue i and adding y to λ yields a partition.

Example 4.1.1. Let $\lambda = (8,5,4,1)$ and $\ell = 3$. Then the residues are filled into the corresponding Young diagram as follows:

$$\lambda = \begin{ytableau} 0 & 1 & 2 & 0 & 1 & 2 & 0 & 1 \\ 2 & 0 & 1 & 2 & 0 \\ 1 & 2 & 0 & 1 \\ 0 \end{ytableau}$$

Here λ has two removable 0-boxes (in the boxes (2,5) and (4,1)), two removable 1-boxes (in the boxes (1,8) and (3,4)), no removable 2-boxes, no addable 0-boxes, two addable 1-boxes (in the boxes (2,6) and (4,2)), and three addable 2-boxes (in the boxes (1,9), (3,5) and (5,1)).

For a fixed i, $(0 \leq i < \ell)$, we place $-$ in each removable i-box and $+$ in each addable i-box. The i-signature of λ is the word of $+$ and $-$'s in the diagram for λ, read from bottom left to top right. The reduced i-signature is the word obtained after repeatedly removing from the i-signature all pairs $-+$. The reduced i-signature is of the form $+\cdots+++---\cdots-$. The boxes corresponding to $-$'s in the reduced i-signature are called *normal i-boxes*, and the boxes corresponding to $+$'s are called *conormal i-boxes.* $\varepsilon_i(\lambda)$ is defined to be the number of normal i-boxes of λ, and $\varphi_i(\lambda)$ is defined to be the number of conormal i-boxes. If a leftmost $-$ exists in the reduced i-signature, the box corresponding to said $-$ is called the *good i-box* of λ. If a rightmost $+$ exists in the reduced i-signature, the box corresponding to said $+$ is called the *cogood i-box.* All of these definitions can be found in Kleshchev's book [9].

Example 4.1.2. Let $\lambda = (8,5,4,1)$ and $\ell = 3$ be as above. Fix $i = 1$. The diagram for λ with removable and addable 1-boxes marked looks like:

$$\begin{ytableau} \; & & & & & & & - \\ & & & & & \none[+] \\ & & & - \\ & \none[+] \end{ytableau}$$

The 1-signature of λ is $+-+-$, so the reduced 1-signature is $+ \qquad -$ and the diagram has a good 1-box in the first row, and a cogood 1-box in the fourth row. Here $\varepsilon_1(\lambda) = 1$ and $\varphi_1(\lambda) = 1$.

We recall the action of the crystal operators on B. The crystal operator $\widetilde{e}_i : B \xrightarrow{i} B \cup \{0\}$ assigns to a partition λ the partition $\widetilde{e}_i(\lambda) = \lambda \backslash x$, where x is the good i-box of λ. If no such box exists, then $\widetilde{e}_i(\lambda) = 0$. It is clear that $\varepsilon_i(\lambda) = max\{k : \widetilde{e}_i^k \lambda \neq 0\}$.

Similarly, $\widetilde{f}_i : B \xrightarrow{i} B \cup \{0\}$ is the operator which assigns to a partition λ the partition $\widetilde{f}_i(\lambda) = \lambda \cup x$, where x is the cogood i-box of λ. If no such box exists, then $\widetilde{f}_i(\lambda) = 0$. It is clear that $\varphi_i(\lambda) = max\{k : \widetilde{f}_i^k \lambda \neq 0\}$.

For i in $\mathbb{Z}/\ell\mathbb{Z}$, we write $\lambda \xrightarrow{i} \mu$ to stand for $\widetilde{f}_i \lambda = \mu$. We say that there is an i-arrow from λ to μ. Note that $\lambda \xrightarrow{i} \mu$ if and only if $\widetilde{e}_i \mu = \lambda$. A maximal chain of consecutive i-arrows is called an i-string. We note that the empty partition $\emptyset$ is the unique highest weight node of the crystal. For a picture of the first few levels of this crystal graph, see [10] for the cases $\ell = 2$ and 3.

Example 4.1.3. Continuing with the above example, $\widetilde{e}_1(8,5,4,1) = (7,5,4,1)$ and $\widetilde{f}_1(8,5,4,1) = (8,5,4,2)$. Also, $\widetilde{e}_1^2(8,5,4,1) = 0$ and $\widetilde{f}_1^2(8,5,4,1) = 0$. The sequence $(7,5,4,1) \xrightarrow{1} (8,5,4,1) \xrightarrow{1} (8,5,4,2)$ is a 1-string of length 3.

4.2. **Crystal operators and ℓ-partitions.** We first recall some well-known facts about the behavior of ℓ-cores in this crystal graph $B(\Lambda_0)$. There is an action of the affine Weyl group $\widetilde{S}_\ell$ on the crystal such that the simple reflection s_i reflects each i-string. In other words, s_i sends a node λ to

$$\begin{cases} \widetilde{f}_i^{\varphi_i(\lambda)-\varepsilon_i(\lambda)}\lambda & \varphi_i(\lambda)-\varepsilon_i(\lambda) > 0 \\ \widetilde{e}_i^{\varepsilon_i(\lambda)-\varphi_i(\lambda)}\lambda & \varphi_i(\lambda)-\varepsilon_i(\lambda) < 0 \\ \lambda & \varphi_i(\lambda)-\varepsilon_i(\lambda) = 0 \end{cases}$$

The ℓ-cores are exactly the $\widetilde{S}_\ell$-orbit of $\emptyset$, the highest weight node. This implies the following Proposition.

Proposition 4.2.1. *If μ is an ℓ-core and $\varepsilon_i(\mu) \neq 0$ then $\varphi_i(\mu) = 0$ and $\widetilde{e}_i^{\varepsilon_i(\mu)}\mu$ is again an ℓ-core. Furthermore, all $\widetilde{e}_i^k\mu$ for $0 < k < \varepsilon_i(\mu)$ are not ℓ-cores. Similarly, if $\varphi_i(\mu) \neq 0$ then $\varepsilon_i(\mu) = 0$ and $\widetilde{f}_i^{\varphi_i(\mu)}\mu$ is an ℓ-core but $\widetilde{f}_i^k\mu$ is not for $0 < k < \varphi_i(\mu)$.*

In this paper, given an ℓ-partition λ, we will determine when $\widetilde{f}_i^k\lambda$ and $\widetilde{e}_i^k\lambda$ are also ℓ-partitions.

The following remarks will help us in the proofs of the upcoming Theorems 4.3.1, 4.3.2 and 4.3.3.

Remark 4.2.2. Suppose λ is a partition. Consider its Young diagram. If any ℓ-rim hook has an upper rightmost box of residue i, then the lower leftmost box has residue $i+1 \mod \ell$. Conversely, a hook length $h^\lambda_{(a,b)}$ is divisible by ℓ if and only if there is an i so that the rightmost box of row a has residue i, and the lowest box of column b has residue $i+1 \mod \ell$.

In Lemma 4.2.4 we will generalize Proposition 4.2.3 to ℓ-partitions.

Proposition 4.2.3. *Let λ be an ℓ-core, and suppose $0 \leq i < \ell$. Then the i-signature for λ is the same as the reduced i-signature.*

Lemma 4.2.4. *Let λ be an ℓ-partition, and suppose $0 \leq i < \ell$. Then the i-signature for λ is the same as the reduced i-signature.*

Proof. Using our decomposition of ℓ-partitions, we assume $\lambda \approx (\mu, r, \kappa)$. Let j be the residue of the box $(1, \lambda_1)$. Then j is also the residue of the boxes (k, λ_k) for $1 \leq k \leq r+1$. So for $i \neq j, j+1$, the only addable or removable i-boxes must be on the core μ (in fact, below row $r+1$), so the i-signature of λ agrees with that of μ. Hence the i-signature of λ is equal to its reduced i-signature by Proposition 4.2.3. When $i = j+1$, the first $r+1$ rows of the diagram have addable i-boxes. We must argue that there is no removable i-box to the left of these. If there were a removable i-box to the left of these addable i-boxes, it would necessarily lie within the core μ (in fact, below row $r+1$), say in box (a,b). Then the hook length $h^\lambda_{(r+1,b)}$ is divisible by ℓ by Remark 4.2.2. But $h^\lambda_{(r+1,b)} = h^\mu_{(1,b)} + \ell\kappa_{r+1}$, so $\ell \mid h^\mu_{(1,b)}$. This contradicts μ being a core (by Proposition 4.2.3). So no such removable i box exists. Finally, suppose that $i = j$, so that the first $r+1$ rows end with i-boxes. In particular the first $r+1$ rows contain no addable i-boxes. Therefore, if there is a removable i-box to the left of an addable i-box, both boxes must occur in the core μ (in fact, below row $r+1$.) As above, this contradicts μ being a core. $\square$

Remark 4.2.5. As a consequence of Lemma 4.2.4, the action of the operators $\widetilde{e}_i$ and $\widetilde{f}_i$ are simplified in the case of ℓ-partitions. Now applying successive $\widetilde{f}_i$'s to λ corresponds to adding all addable boxes of residue i from right to left. Similarly, applying successive $\widetilde{e}_i$'s to λ corresponds to removing all removable boxes of residue i from left to right.

In the following Theorems 4.3.1, 4.3.2 and 4.3.3, we implicitly use Remark 4.2.2 to determine when a hook length is divisible by ℓ, and Remark 4.2.5 when applying $\widetilde{e}_i$ and $\widetilde{f}_i$ to λ. Unless it is unclear from the context, for the rest of the paper $\varphi = \varphi_i(\lambda)$ and $\varepsilon = \varepsilon_i(\lambda)$.

Remark 4.2.6. Suppose $\lambda \approx (\mu, r, \kappa)$. When viewing μ embedded in λ, we note that if a box $(a, b) \in \mu \subset \lambda$ has residue $i \mod \ell$ in λ, then it has residue $i - r \mod \ell$ in μ.

For a partition $\lambda = (\lambda_1, \lambda_2, \dots, \lambda_k)$ of length k, we define $\overline{\lambda} = (\lambda_2, \dots, \lambda_k)$, $\hat{\lambda} = (\lambda_1, \lambda_1, \lambda_2, \lambda_3, \dots, \lambda_k)$ and $\lambda + 1 = (\lambda_1 + 1, \lambda_2 + 1, \dots, \lambda_k + 1)$. Note that if λ is an ℓ-core, then so is $\overline{\lambda}$.

4.3. ℓ-partitions in the crystal $B(\Lambda_0)$.

Theorem 4.3.1. *Suppose that λ is an ℓ-partition and $0 \le i < \ell$. Then*

1. *$\widetilde{f}_i^{\varphi}\lambda$ is an ℓ-partition,*
2. *$\widetilde{e}_i^{\varepsilon}\lambda$ is an ℓ-partition.*

Proof. We will prove only (1), as (2) is similar. Recall all addable i-boxes of λ are conormal by Lemma 4.2.4. The proof of (1) relies on the decomposition of the ℓ-partition as in Section 3.2. Let $\lambda \approx (\mu, r, \kappa)$. We break the proof of (1) into three cases:

(a) If the first row of μ embedded in λ does not have an addable i-box then we cannot add an i-box to the first $r+1$ rows of λ. Hence $\varphi = \varphi_{i-r}(\mu)$. Therefore the decomposition of $\widetilde{f}_i^{\varphi}\lambda$ has the same r and κ as λ, and μ will be replaced by $\widetilde{f}_{i-r}^{\varphi}\mu$, which is still a core by Proposition 4.2.3. Hence $\widetilde{f}_i^{\varphi}\lambda \approx (\widetilde{f}_{i-r}^{\varphi}\mu, r, \kappa)$.

(b) If the first row of μ embedded in λ does have an addable i-box and $\mu_1 - \mu_2 < \ell - 2$, then the first $r+1$ rows of λ have addable i-boxes. Also some rows of μ will have addable i-boxes. $\widetilde{f}_i^{\varphi}$ adds an i-box to the first r rows of λ, plus adds to any addable i-boxes in the core μ. Note that $\varphi_{i-r}(\mu) = \varphi - r$. Since $\mu_1 - \mu_2 < \ell - 2$, the first and second rows of $\widetilde{f}_{i-r}^{\varphi-r}\mu$ differ by at most $\ell - 2$. Therefore $\widetilde{f}_i^{\varphi}\lambda \approx (\widetilde{f}_{i-r}^{\varphi-r}\mu, r, \kappa)$.

(c) If the first row of μ embedded in λ does have an addable i-box and $\mu_1 - \mu_2 = \ell - 2$, then $\widetilde{f}_i^{\varphi}$ will add the addable i-box in the $r+1^{st}$ row (i.e. the first row of μ). Since the $(r+2)^{nd}$ row does not have an addable i-box, we know that the $(r+1)^{st}$ and $(r+2)^{nd}$ rows of $\widetilde{f}_i^{\varphi}(\lambda)$ differ by $\ell - 1$. Therefore $\widetilde{f}_i^{\varphi}\lambda \approx (\overline{\widetilde{f}_{i-r}^{\varphi-r}\mu}, r+1, \kappa)$ is an ℓ-partition.

$\square$

Theorem 4.3.2. *Suppose that λ is an ℓ-partition. Then*

1. $\widetilde{f}_i^k\lambda$ *is not an ℓ-partition for* $0 < k < \varphi - 1$,
2. $\widetilde{e}_i^k\lambda$ *is not an ℓ-partition for* $1 < k < \varepsilon$.

Proof. If $0 < k < \varphi - 1$ then there are at least two conormal i-boxes in $\widetilde{f}_i^k\lambda$ and at least one normal i-box, to the right of the two conormal i-boxes by Lemma 4.2.4. Label the conormal boxes n_1 and n_2, with n_1 to the left of n_2. Call the normal box n_3. Then the hook length in the column of n_1 and row of n_3 is a multiple of ℓ, but the hook length in the column of n_1 and row of n_2 is not a multiple of ℓ by Remark 4.2.2. By Theorem 2.1.6, $\widetilde{f}_i^k\lambda$ is not an ℓ-partition. The proof of (2) is similar to (1). □

The above theorems told us the position of an ℓ-partition relative to the i-string which it sits on in the crystal $B(\Lambda_0)$. If an ℓ-partition occurs on an i-string, then both ends of the i-string are also ℓ-partitions. Furthermore, the only places ℓ-partitions can occur are at the ends of i-strings or possibly one position before the final node. The next theorem describes when this latter case occurs.

Theorem 4.3.3. *Suppose that $\lambda \approx (\mu, r, \kappa)$ is an ℓ-partition. Then*

1. *If $\varphi > 1$ then $\widetilde{f}_i^{\varphi-1}\lambda$ is an ℓ-partition if and only if*

$$(\dagger) \qquad \kappa_{r+1} = 0, \text{ the first row of } \lambda \text{ has a conormal } i\text{-box, and } \varphi = r+1.$$

2. *If $\varepsilon > 1$ then $\widetilde{e}_i\lambda$ is an ℓ-partition if and only if*

($\ddagger$) *the first row of λ has a conormal $(i+1)$-box and either $\varepsilon = r$ and $\kappa_r = 0$, or $\varepsilon = r+1$ and $\kappa_{r+1} = 0$.*

Proof. We first prove (1) and then derive (2) from (1).

If λ satisfies condition ($\dagger$) then $\widetilde{f}_i^{\varphi-1}\lambda \approx (\widehat{\mu}, r-1, \kappa+1)$, so it is an ℓ-partition. Conversely:

(a) If the first part of λ has a conormal j-box, with $j \neq i$, call this box n_1. If $j = i+1$ then the box $(r+1, \lambda_{r+1})$ has residue i. If an addable i-box exists, say at (a, b), it must be below the first $r+1$ rows. But then the hook length $h^{\mu}_{(r+1,b)}$ is divisible by ℓ. This implies that μ is not a core. So we assume $j \neq i+1$. Then $\widetilde{f}_i^{\varphi-1}\lambda$ has at least one normal i-box n_2 and exactly one conormal i-box n_3 with n_3 left of n_2 left of n_1. The hook length of the box in the column of n_3 and row n_2 is divisible by ℓ, but the hook length in the box of column n_3 and row n_1 is not (by Remark 4.2.2). By Theorem 2.1.6, $\widetilde{f}_i^{\varphi-1}\lambda$ is not an ℓ-partition.

(b) By (a), we can assume that the first row has a conormal i-box. If $\varphi \neq r+1$ then row $r+2$ of $\widetilde{f}_i^{\varphi-1}\lambda$ will end in a j-box, for some $j \neq i$. Call this box n_1. Also let n_2 be any normal i-box in $\widetilde{f}_i^{\varphi-1}\lambda$ and n_3 be the unique conormal i-box. Then the box in the row of n_1 and column of n_3 has a hook length which is not divisible by ℓ, but the box in the row of n_2 and column of n_3 has a hook length which is (by Remark 4.2.2). By Theorem 2.1.6, $\widetilde{f}_i^{\varphi-1}\lambda$ is not an ℓ-partition.

(c) Suppose $\kappa_{r+1} \neq 0$. By (a) and (b), we can assume that $\varphi = r+1$ and that the first row of λ has a conormal i-box. Then the difference between λ and $\widetilde{f}_i^{\varphi-1}\lambda = \widetilde{f}_i^{r}\lambda$ is an added box in each of the first r rows. Remove $\kappa_r - \kappa_{r+1} + 1$ horizontal ℓ-rim hooks from row r of $\widetilde{f}_i^{\varphi-1}\lambda$. Call the remaining partition ν. Then $\nu_r = \nu_{r+1} = \mu_1 + \ell\kappa_{r+1}$. Hence a removable non-horizontal ℓ-rim hook exists in ν taking the rightmost box from row r with the rightmost $\ell-1$ boxes from row $r+1$. Thus $\widetilde{f}_i^{\varphi-1}(\lambda)$ is not an ℓ-partition.

To prove (2), we note that by Theorem (4.3.2) that if $\varphi \neq 0$ and $\varepsilon > 1$ then $\widetilde{e}_i\lambda = \widetilde{e}_i^2\widetilde{f}_i\lambda$ cannot be an ℓ-partition. Hence we only consider λ so that $\varphi_i(\lambda) = 0$. But then $\widetilde{f}_i^{\varphi_i(\widetilde{e}_i^\varepsilon(\lambda))-1}\widetilde{e}_i^\varepsilon\lambda = \widetilde{f}_i^{\varepsilon-1}\widetilde{e}_i^\varepsilon\lambda = \widetilde{e}_i\lambda$. From this observation, it is enough to show that λ satisfies (‡) if and only if $\widetilde{e}_i^\varepsilon\lambda$ satisfies (†). The proof of this follows a similar line as the above proofs, so it will be left to the reader. ☐

Example 4.3.4. Fix $\ell = 3$. Let $\lambda = (9, 4, 2, 1, 1) \approx ((2, 1, 1), 2, (1))$.

$$\lambda = \begin{array}{|c|c|c|c|c|c|c|c|c|}\hline 0 & 1 & 2 & 0 & 1 & 2 & 0 & 1 & 2 \\ \hline 2 & 0 & 1 & 2 \\ \cline{1-4} 1 & 2 \\ \cline{1-2} 0 \\ \cline{1-1} 2 \\ \cline{1-1} \end{array}$$

Here $\varphi_0(\lambda) = 3$. $\widetilde{f}_0\lambda = (10, 4, 2, 1, 1)$ is not a 3-partition, but $\widetilde{f}_0^2\lambda = (10, 5, 2, 1, 1) \approx ((2, 2, 1, 1), 1, (2, 1))$ and $\widetilde{f}_0^3\lambda = (10, 5, 3, 1, 1) \approx ((1, 1), 3, (1))$ are 3-partitions.

5. Representation Theoretic Proof of Theorem 4.3.1

This proof relies heavily on the work of Grojnowski, Kleshchev et. al. We recall some notation from [5] but repeat very few definitions below.

5.1. **Definitions and preliminaries.** In the category Rep_n of finite dimensional representations of the finite Hecke algebra $H_n(q)$, we define the Grothendieck group $K(Rep_n)$ to be the group generated by isomorphism classes of finite dimensional representations, with relations $[\mathcal{M}_1]+[\mathcal{M}_3] = [\mathcal{M}_2]$ if there exists an exact sequence $0 \to \mathcal{M}_1 \to \mathcal{M}_2 \to \mathcal{M}_3 \to 0$. This is a finitely generated group with generators corresponding to the irreducible representations of $H_n(q)$. The equivalence class corresponding to the module $\mathcal{M}$ is denoted $[\mathcal{M}]$.

Just as S_n can be viewed as the subgroup of S_{n+1} of permutations which fix $n+1$, $H_n(q)$ can be viewed as a subalgebra of $H_{n+1}(q)$ (the generators $T_1, T_2, \ldots, T_{n-1}$ generate a subalgebra isomorphic to $H_n(q)$). Let $\mathcal{M}$ be a finite dimensional representation of $H_{n+1}(q)$. Then it makes sense to view $\mathcal{M}$ as a representation of $H_n(q)$. This module is called the *restriction of* $\mathcal{M}$ *to* $H_n(q)$, and is denoted $Res_{H_n(q)}^{H_{n+1}(q)}\mathcal{M}$. Similarly, we can define the induced representation of $\mathcal{M}$ by $Ind_{H_n(q)}^{H_{n+1}(q)}\mathcal{M} = H_{n+1}(q) \otimes_{H_n(q)} \mathcal{M}$.

To shorten notation, $Res_{H_b(q)}^{H_a(q)}$ will be written Res_b^a, and $Ind_{H_b(q)}^{H_a(q)}$ will be written as Ind_b^a.

If λ and μ are partitions, it is said that μ covers λ, (written $\mu \succ \lambda$) if the Young diagram of λ is contained in the Young diagram of μ and $|\mu| = |\lambda| + 1$.

Proposition 5.1.1. *Let λ be a partition of n and S^λ be the Specht module corresponding to λ. Then*

$$[Ind_n^{n+1}S^\lambda] = \sum_{\mu \succ \lambda}[S^\mu]$$

We consider functors $\widetilde{e}_i : Rep_n \to Rep_{n-1}$ and $\widetilde{f}_i : Rep_n \to Rep_{n+1}$ which commute with the crystal action on partitions in the following sense (see [5] for definitions and details).

Theorem 5.1.2. *Let λ be an ℓ-regular partition. Then*

(1) $\widetilde{e}_i D^{\lambda} = D^{\widetilde{e}_i \lambda}$
(2) $\widetilde{f}_i D^{\lambda} = D^{\widetilde{f}_i \lambda}$

Fix a function $\alpha : \{0, 1, \ldots, \ell-1\} \to \mathbb{Z}_+$. The *Ariki-Koike, or cyclotomic Hecke algebra* $H_n^{\alpha}(q)$ is defined to be the algebra with generators $T_0, T_1, \ldots, T_{n-1}$ and relations

$$\begin{array}{ll} T_iT_j = T_jT_i & \text{for } |i-j| > 1 \text{ and } n > i, j > 0 \\ T_iT_{i+1}T_i = T_{i+1}T_iT_{i+1} & \text{for } 0 < i < n-1 \\ T_i^2 = (q-1)T_i + q & \text{for } 0 < i \leq n-1 \\ T_0T_1T_0T_1 = T_1T_0T_1T_0 & \\ \displaystyle\prod_{i=0}^{\ell-1}(T_0 - q^i)^{\alpha(i)} = 0. & \end{array}$$

As before, $H_n^{\alpha}(q)$ is a subalgebra of $H_{n+1}^{\alpha}(q)$. Rep_n^{α} is defined to be the category of finite dimensional representations of $H_n^{\alpha}(q)$. Similarly we can consider the Grothendieck group $K(Rep_n^{\alpha})$. We now consider the functors $f_i^{\alpha} : Rep_n^{\alpha} \to Rep_{n+1}^{\alpha}$ and $e_i^{\alpha} : Rep_n^{\alpha} \to Rep_{n-1}^{\alpha}$ which refine induction and restriction (for a definition of these functors, see [5]). For a representation $\mathcal{M} \in Rep_n^{\alpha}$ let $\varepsilon_i^{\alpha}(\mathcal{M}) = max\{k : (e_i^{\alpha})^k \mathcal{M} \neq 0\}$ and $\varphi_i^{\alpha}(\mathcal{M}) = max\{k : (f_i^{\alpha})^k \mathcal{M} \neq 0\}$. Grojnowski concludes the following theorem.

Theorem 5.1.3. *Let $\mathcal{M}$ be a finite dimensional representation of $H_n^{\alpha}(q)$.*

(1) $Ind_{H_n^{\alpha}(q)}^{H_{n+1}^{\alpha}(q)} \mathcal{M} = \bigoplus_i f_i^{\alpha}\mathcal{M}$; $\qquad Res_{H_n^{\alpha}(q)}^{H_{n+1}^{\alpha}(q)} \mathcal{M} = \bigoplus_i e_i^{\alpha}\mathcal{M}$
(2) $[f_i^{\varphi}\mathcal{M}] = \varphi![\widetilde{f}_i^{\varphi}\mathcal{M}]$; $\qquad [e_i^{\varepsilon}\mathcal{M}] = \varepsilon![\widetilde{e}_i^{\varepsilon}\mathcal{M}]$

For a module D^{μ} the *central character* $\chi(D^{\mu})$ can be identified with the multiset of residues of the partition μ. The following theorem justifies the notation $\chi(S^{\mu})$ as well.

Theorem 5.1.4. *All composition factors of the Specht module S^{λ} have the same central character.*

Theorem 5.1.5. $\chi(f_i(D^{\lambda})) = \chi(D^{\lambda}) \cup \{i\}$; $\qquad \chi(e_i(D^{\lambda})) = \chi(D^{\lambda}) \setminus \{i\}$.

Define a function

$$\Lambda_0(i) = \begin{cases} 1 & \text{if } i = 0 \\ 0 & \text{if } i \neq 0. \end{cases}$$

Then the finite Hecke algebra $H_n(q)$ and the cyclotomic Hecke algebra $H_n(q)^{\Lambda_0}$ are isomorphic. This gives us functors $f_i^{\Lambda_0}$ and $e_i^{\Lambda_0}$. We are now ready to present a representation theoretic proof of Theorem 4.3.1, which states that if λ is an ℓ-partition lying at one end of an i-string in the crystal $B(\Lambda_0)$, then the opposite end of the i-string through λ is also an ℓ-partition.

5.2. **A representation theoretic proof of Theorem 4.3.1.**

Alternate Proof of Theorem 4.3.1. Suppose λ is an ℓ-partition and $|\lambda| = n$. Recall that by the result of James and Mathas [7] combined with Theorem 2.1.6, $S^\lambda = D^\lambda$ if and only if λ is an ℓ-partition. Let F denote the number of addable i-boxes of λ and let ν denote the partition corresponding to λ plus all addable i-boxes.

First, we induce S^λ from $H_n(q)$ to $H_{n+F}(q)$. Applying Proposition 5.1.1 F times yields

$$[Ind_n^{n+F} S^\lambda] = \sum_{\mu_F \succ \mu_{F-1} \succ \cdots \succ \mu_1 \succ \lambda} [S^{\mu_F}].$$

Note $[S^\nu]$ occurs in this sum with coefficient $F!$ (add the i-boxes in any order), and everything else in this sum has different central character than S^ν. Hence the direct summand which has the same central character as S^ν (i.e. the central character of λ with F more i's) is $F![S^\nu]$ in $K(Rep_{n+F})$.

We next apply (1) from Theorem 5.1.3 F times to obtain

$$[Ind_n^{n+F} D^\lambda] = \bigoplus_{i_1,\ldots,i_F} [f_{i_1}^{\Lambda_0} \ldots f_{i_F}^{\Lambda_0} D^\lambda].$$

Again, the direct summand with central character $\chi(S^\nu)$ is exactly $[(f_i^{\Lambda_0})^F D^\lambda]$ in $K(Rep_{n+F})$. Since λ is an ℓ-partition, $S^\lambda = D^\lambda$, so $Ind_n^{n+F} S^\lambda = Ind_n^{n+f} D^\lambda$ and we have shown that $F![S^\nu] = [(f_i^{\Lambda_0})^F D^\lambda]$.

Since $S^\lambda = D^\lambda$ and $(f_i^{\Lambda_0})^F D^\lambda \neq 0$, we know that $F \leq \varphi$. Similarly, since $Ind_n^{n+F+1} S^\lambda$ has no composition factors with central character $\chi(S^\lambda)$ union $F+1$ many i's, we know that $F \geq \varphi$. Hence $F = \varphi$.

By part 2 of Theorem 5.1.3, $[(f_i^{\Lambda_0})^\varphi D^\lambda] = \varphi![\widetilde{f}_i^{\varphi} D^\lambda]$. Then by Theorem 5.1.2, $[S^\nu] = [D^{\widetilde{f}_i^{\varphi}\lambda}]$.

Since $F = \varphi$, $\nu = \widetilde{f}_i^{\varphi}\lambda$, so in particular ν is ℓ-regular and $S^\nu = D^\nu$. Hence $\widetilde{f}_i^{\varphi}\lambda = \nu$ is an ℓ-partition.

The proof that $\widetilde{e}_i^{\varepsilon_i(\lambda)}\lambda$ is an ℓ-partition follows similarly, with the roles of induction and restriction changed in Proposition 5.1.1, and the roles of e_i and f_i changed in Theorem 5.1.3.

□

We do not yet have representation theoretic proofs of our other Theorems 4.3.2 and 4.3.3. We expect Theorem 4.3.2 to be true over any field. In Theorem 4.3.3 the conditions (†) and (‡) will change for different fields, so any representation theoretic proof of this theorem should distinguish between these different cases.

6. CONJECTURES AND FURTHER WORK

We will end by mentioning some open problems and further work we have done concerning ℓ-partitions. Recent results of Fayers ([4]) and Lyle ([11]) have given combinatorial conditions which characterize partitions λ so that the corresponding Specht module S^λ of $H_n(q)$ is irreducible when q is a primitive ℓth root of unity, without the condition that the λ be ℓ-regular. Such partitions are called $(\ell, 0)$-J.M. partitions in [4]. We currently have a result for $(\ell, 0)$-J.M. partitions which is analogous to Theorem 2.1.6 and a construction of $(\ell, 0)$-J.M. partitions similar to that in Section 3.2. Analogues to Theorems 4.3.1, 4.3.2 and 4.3.3 also hold for all

$(\ell, 0)$-JM partitions (see [4] for a definition of $(\ell, 0)$-JM partitions, the ℓ-singular analog of an $(\ell, 0)$-Carter partition).

Another possible direction to this work would be to find such results for $\mathbb{F}_p S_n$. Here the theorems corresponding to Theorems 4.3.1 and 4.3.2 should still hold, but condition (†) in Theorem 4.3.3 must be changed. We do not yet know of a condition to replace (†). However, it has come to our attention that Cossey, Ondrus and Vinroot (see [2]) have a construction for the case of the symmetric group in characteristic p which is an analog of our construction of ℓ-partitions from Section 3.2. Their theorem should be the starting point for any attempt at generalizing our results to this case.
